Title Robust Empirical Bayes Confidence Intervals

Version 1.0.0.9000

Description Computes empirical Bayes confidence estimators and confidence intervals in a normal means model. The intervals are robust in the sense that they achieve correct coverage regardless of the distribution of the means. If the means are treated as fixed, the intervals have an average coverage guarantee. The implementation is based on Armstrong, Kolesár and Plagborg-Møller (2022) <[doi:10.3982/ECTA18597](https://doi.org/10.3982/ECTA18597)>.

-------	---

cva	<i>Compute average coverage critical value under moment constraints.</i>
-----	--------------------------------------------------------------------------

Description

Computes the critical value $cva_{\alpha}(m_2, \kappa)$ from Armstrong, Kolesár, and Plagborg-Møller (2022).

Usage

```
cva(m2, kappa = Inf, alpha = 0.05, check = TRUE)
```

Arguments

m2	Bound on second moment of the normalized bias, m_2
kappa	Bound on the kurtosis of the normalized bias, κ
alpha	Determines confidence level, $1 - \alpha$.
check	If TRUE, verify accuracy of the solution by checking that the implied least favorable distribution satisfies the m2 and kappa constraints and yields the same non-coverage rate. If this fails (perhaps due to numerical accuracy issues), solve a finite-grid approximation (by discretizing the support of the normalized bias) to the primal linear programming problem, and check that it agrees with the dual solution.

Value

Returns a list with 4 components:

cv Critical value for constructing two-sided confidence intervals.

alpha The argument alpha.

x Support points for the least favorable distribution for the squared normalized bias, b^2 .

p Probabilities associated with the support points.

Examples

```
# Usual critical value
cva(m2=0, kappa=Inf, alpha=0.05)
# Larger critical value that takes bias into account. Only uses second moment
# constraint on normalized bias.
cva(m2=4, kappa=Inf, alpha=0.05)
# Add a constraint on kurtosis. This tightens the critical value.
cva(m2=4, kappa=3, alpha=0.05)
```

CZ

*Neighborhood effects data from Chetty and Hendren (2018)***Description**

This dataset contains a subset of the publicly available data from Chetty and Hendren (2018). It contains raw estimates and standard errors of neighborhood effects at the commuting zone level

Usage

CZ

Format

A data frame with 741 rows corresponding to commuting zones (CZ) and 10 columns corresponding to the variables:

cz Commuting zone ID

czname Name of CZ

state 2-digit state code

pop Population according to the year 2000 Census

theta25 Fixed-effect estimate of the causal effect of living in the CZ for one year on children's percentile rank in the national distribution of household earnings at age 26 relative to others in the same birth cohort for children growing up with parents at the 25th percentile of national income distribution

theta75 Fixed-effect estimate of the causal effect of living in the CZ for one year on children's percentile rank in the national distribution of household earnings at age 26 relative to others in the same birth cohort for children growing up with parents at the 75th percentile of national income distribution

se25 Standard error of theta25

se75 Standard error of theta75

stayer25 Average percentile rank in the national distribution of household earnings at age 26 relative to others in the same birth cohort for stayers (children who grew up in the CZ and did not move) with parents at the 25th percentile of national income distribution.

stayer75 Average percentile rank in the national distribution of household earnings at age 26 relative to others in the same birth cohort for stayers (children who grew up in the CZ and did not move) with parents at the 75th percentile of national income distribution.

ebci	<i>Compute empirical Bayes confidence intervals by shrinking toward regression</i>
------	------------------------------------------------------------------------------------

Description

Computes empirical Bayes estimators based on shrinking towards a regression, and associated robust empirical Bayes confidence intervals (EBCIs), as well as length-optimal robust EBCIs.

Usage

```
ebci(
  formula,
  data,
  se,
  weights = NULL,
  alpha = 0.1,
  kappa = NULL,
  wopt = FALSE,
  fs_correction = "PMT"
)
```

Arguments

formula	object of class "formula" (or one that can be coerced to that class) of the form $Y \sim \text{predictors}$, where Y is a preliminary unbiased estimator, and predictors are predictors X that guide the direction of shrinkage. For shrinking toward the grand mean, use $Y \sim 1$, and for shrinking toward \emptyset use $Y \sim \emptyset$
data	optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the preliminary estimator Y and the predictors. If not found in data, these variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
se	Standard errors σ associated with the preliminary estimates Y
weights	An optional vector of weights to be used in the fitting process in computing δ , μ_2 and κ . Should be <code>NULL</code> or a numeric vector.
alpha	Determines confidence level, $1 - \alpha$.
kappa	If non- <code>NULL</code> , use pre-specified value for the kurtosis κ of $\theta - X'\delta$ (such as <code>Inf</code>), instead of computing it.

wopt	If TRUE, also compute length-optimal robust EBCIs. These are robust EBCIs centered at estimates with the shrinkage factor w_i chosen to minimize the length of the resulting EBCI.
fs_correction	Finite-sample correction method used to compute μ_2 and κ . These corrections ensure that we do not shrink the preliminary estimates Y all the way to zero. If "PMT", use posterior mean truncation, if "FPLIB" use limited information Bayesian approach with a flat prior, and if "none", truncate the estimates at 0 for μ_2 and 1 for κ .

Value

Returns a list with the following components:

mu2 Estimated second moment of $\theta - X'\delta$, μ_2 . Vector of length 2, the first element corresponds to the estimate after the finite-sample correction as specified by fs_correction, the second element is the uncorrected estimate.

kappa Estimated kurtosis κ of $\theta - X'\delta$. Vector of length 2 with the same structure as mu2.

delta Estimated regression coefficients δ

X Matrix of regressors

alpha Determines confidence level $1 - \alpha$ used.

df Data frame with components described below.

df has the following components:

w_eb EB shrinkage factors, $\mu_2/(\mu_2 + \sigma_i^2)$

w_opt Length-optimal shrinkage factors

ncov_pa Maximal non-coverage of parametric EBCIs

len_eb Half-length of robust EBCIs based on EB shrinkage, so that the intervals take the form `cbind(th_eb-len_eb, th_eb+len_eb)`

len_op Half-length of robust EBCIs based on length-optimal shrinkage, so that the intervals take the form `cbind(th_op-len_op, th_op+len_op)`

len_pa Half-length of parametric EBCIs, which take the form `cbind(th_eb-len_pa, th_eb+len_a)`

len_us Half-length of unshrunk CIs, which take the form `cbind(th_us-len_us, th_us+len_us)`

th_us Unshrunk estimate Y

th_eb EB estimate.

th_op Estimate based on length-optimal shrinkage.

se Standard error σ , as supplied by the argument se

weights Weights used

residuals The residuals $Y_i - X_i\delta$
